

**Arpit Singh**

**19BCG10069**

**Kaiburr – Task 3**

**Technical Task**

**(Placement)**

**GitHub Link:** [https://github.com/TSM-ArpitSG/Kaiburr/tree/main/Kaibur\\_Tasks/Task\\_3](https://github.com/TSM-ArpitSG/Kaiburr/tree/main/Kaibur_Tasks/Task_3)

**Task 3:**

**Kubernetes:**

Use the application that you created in task #1 or task #2. Create dockerfiles and build docker images. Create kubernetes yaml manifests for the application (at least a deployment and a service). It's ok to expose the application with a LoadBalancer or NodePort service or with an ingress. Spin up a single-node local Kubernetes cluster (Docker Desktop, Kind or Minikube) or use a managed cluster like EKS, AKS, GKE etc. Deploy MongoDB to the cluster (it's ok to use a community helm chart for this, any other approach is fine as well). Then deploy the application to the cluster by applying your manifests. The following requirements should be fulfilled:

- you can bring your application up by applying your yaml manifests
- mongodb is running in a separate pod
- the application should take mongo connection details from the environment variables
- the app endpoints should be available from your host machine
- a persistent volume should be used to store the MongoDB data. I.e., when you delete the MongoDB pod the records in the db should not disappear.

## Steps-(<https://hub.docker.com/repository/docker/arpitsh/myapp/general>):

### 1. Create Dockerfiles:

To **containerize your application**, you need to create **Dockerfiles that specify the image configuration**. You need to create “**two Dockerfiles**”: one for your ‘**application**’ and one for the ‘**MongoDB**’ instance that you will run in a separate pod. The Dockerfile for your application should include the necessary **dependencies, environment variables, and any other configuration** files that your application requires. The Dockerfile for MongoDB should include the necessary **configuration files and the MongoDB server**.

#### a. Download Docker:

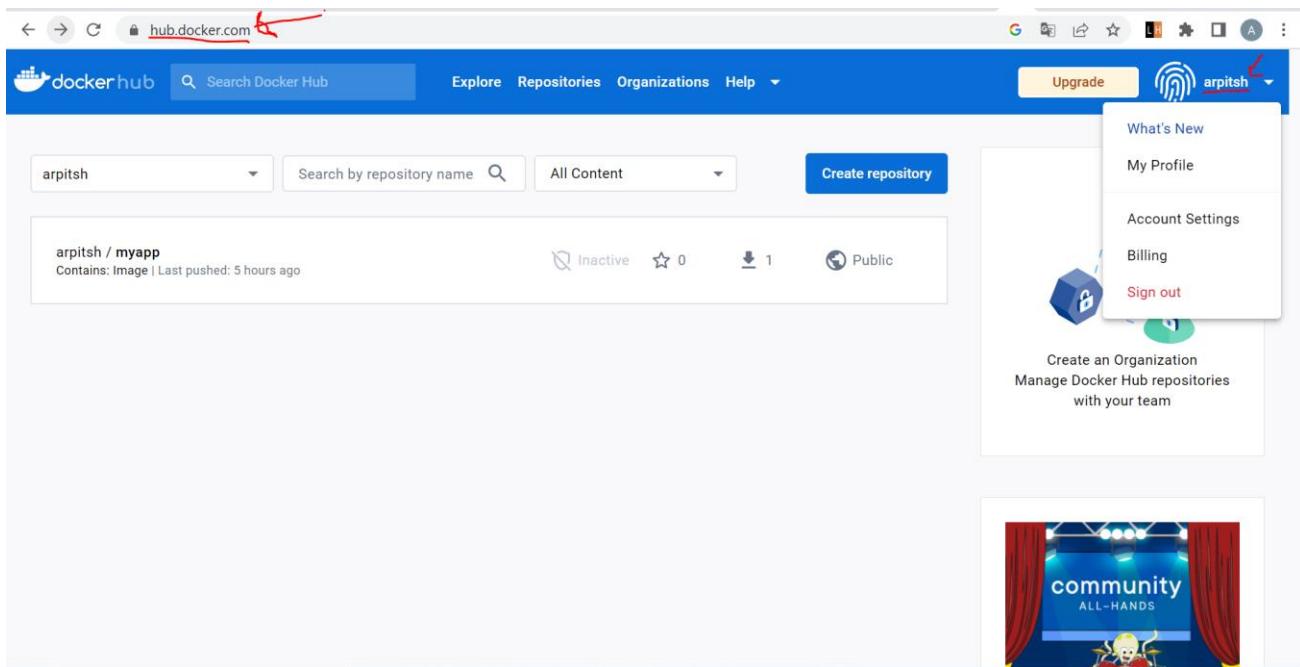

- i. Go to the official Docker website at “<https://www.docker.com/get-started>” and click on the “**Download**” button.
- ii. Choose your operating system (‘**Windows**’, macOS, or Linux) and follow the instructions to download the ‘**Docker installer**’ for your OS.
- iii. Once the installer is downloaded, run it and follow the installation prompts to **complete the installation process**.
- iv. Configure Env Variable to add : “**C:\Program Files\ Docker**”

#### b. ‘**Successful Installation**’ of Docker can be checked as follows:

```
C:\Users\User>docker -v
Docker version 20.10.23, build 7155243
```

#### c. Create a ‘Docker Hub’ account:

- i. Go to the Docker Hub website at ‘<https://hub.docker.com/>’ and click on the “**Sign up**” button.
- ii. Enter your email address and choose a password, then click on the “**Sign up for Docker Hub**” button.
- iii. Check your email for a verification link and click on it to verify your account.
- iv. Once your account is verified, you can **log in to Docker Hub** and start using it to share and **store your Docker images**.

#### d. **Creating the Dockerfiles:**

- Open up the “**root directory**” of your application.
  - In this case we are deploying the **Rest API** that we created in **Task 1**. Therefore, the root directory is like:  
“**C:\Users\User\Desktop\Kaiburr-main\Kaibur-Tasks\Task 1**”.
  - In this directory “**add a file named Dockerfile**”:
- In this file add the ‘**Following code**’:

```

# Use an official Python runtime as a parent image
FROM python:3.9

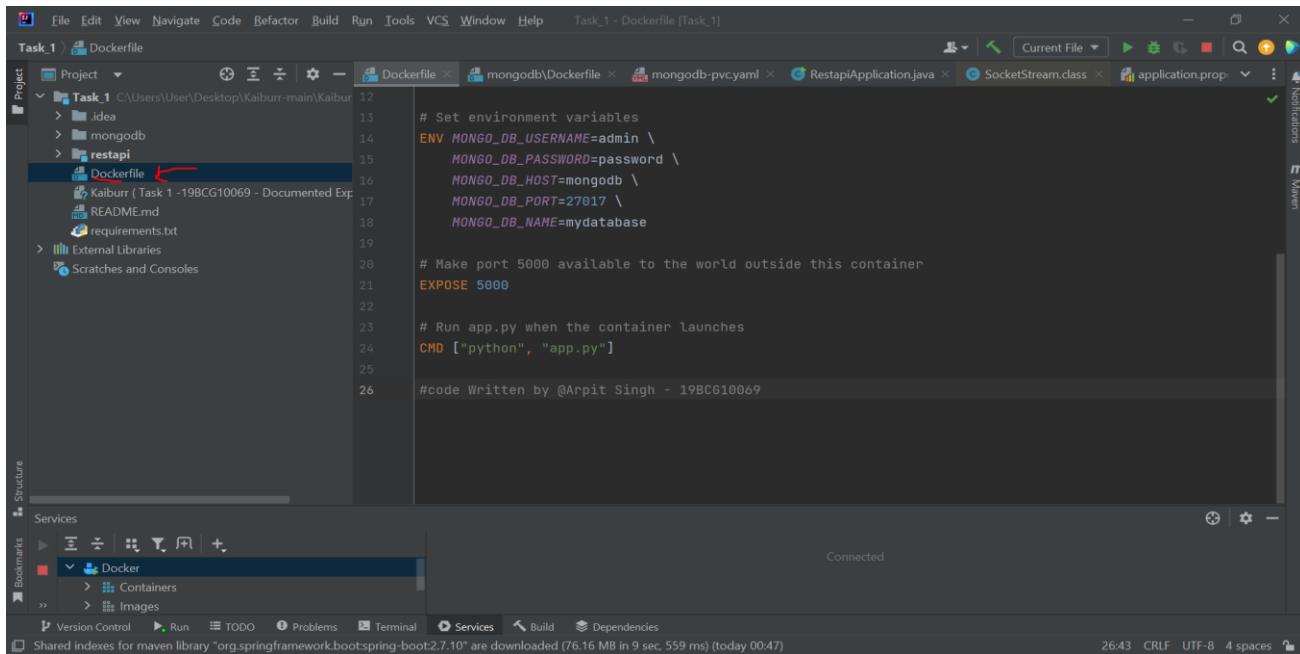

# Set the working directory to /app
WORKDIR /app

# Copy the current directory contents into the container at /app
COPY . /app

# Install any needed packages specified in requirements.txt
RUN pip install --trusted-host pypi.python.org -r requirements.txt

# Set environment variables
ENV MONGO_DB_USERNAME=admin \
    MONGO_DB_PASSWORD=password \
    MONGO_DB_HOST=mongodb \
    MONGO_DB_PORT=27017 \
    MONGO_DB_NAME=mydatabase

# Make port 5000 available to the world outside this container
EXPOSE 5000
  
```

```

26:43 CRLF UTF-8 4 spaces

- In this file, you will define the steps required to build a **Docker image for your application**. This Dockerfile starts with a **base image that has Java 11** installed (FROM **adoptopenjdk/openjdk11:jre-11.0.12\_7-alpine**). It then **sets the working directory to /app**, copies the application jar file to the container, and sets the **necessary environment variables for connecting to the MongoDB** instance. It exposes **port 8080** and starts the application using the command **java -jar my-application.jar**.

iii. Next we create a **Dockerfile for MongoDB**:

- From the **Root Directory** “**C:\Users\User\Desktop\Kaiburr-main\Kaibur\_Tasks\Task\_1**” **create another directory named “mongodb”**.
- Inside this “**mongodb**” Create a “**Dockerfile**” with the **‘Following code’**

The screenshot shows the IntelliJ IDEA interface with a project named "Task\_1". Inside the project, there is a "mongodb" directory containing a "Dockerfile". The "Dockerfile" is open in the editor and contains the following code:

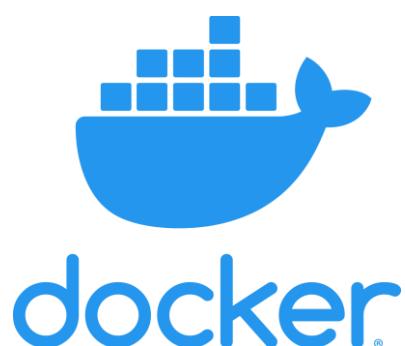

```

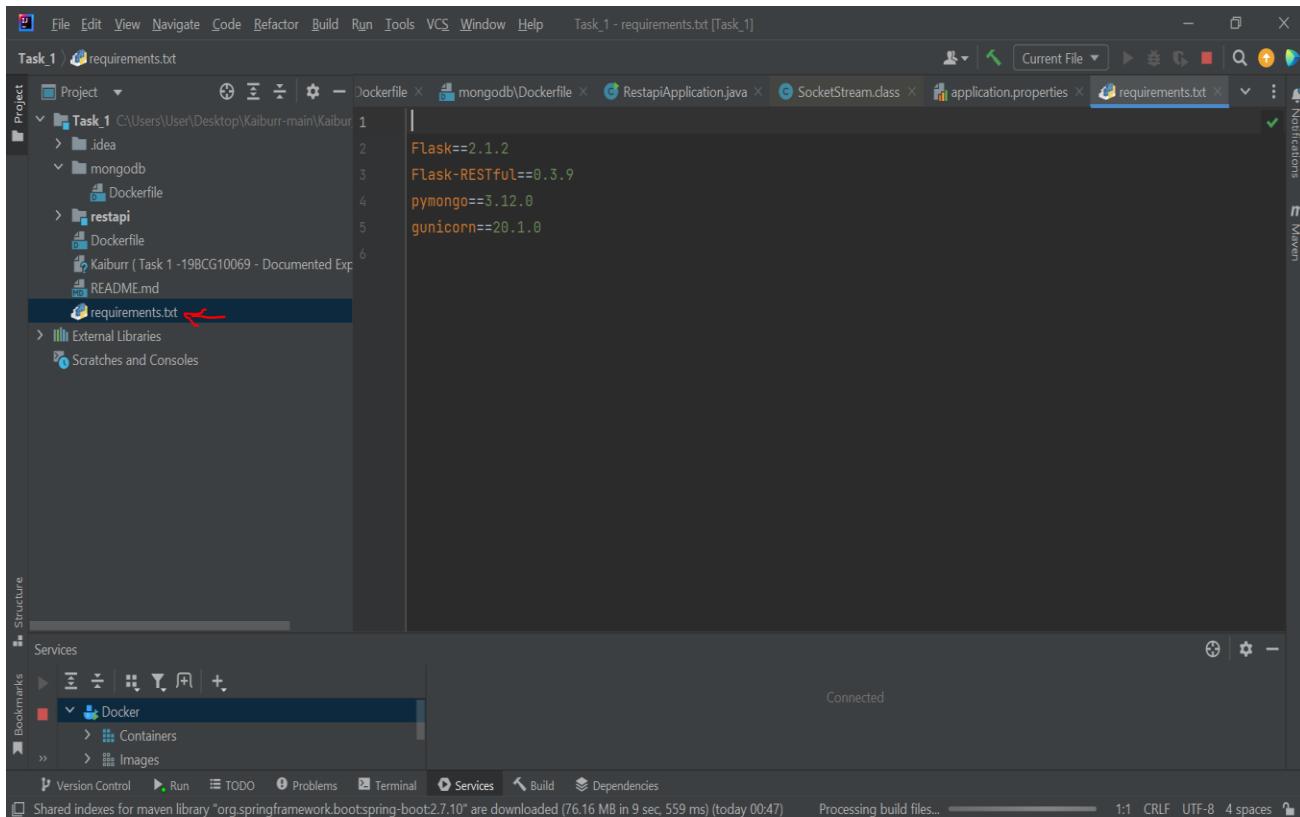

FROM mongo:4.4.5
# Define working directory
WORKDIR /data
# Define mountable directory
VOLUME /data/db
#
# Expose MongoDB port
EXPOSE 27017
#
# Set command to run when launching the container
CMD ["mongod"]
#Code Written by @Arpit Singh - 19BCG10069

```

The "Services" tool window is visible at the bottom, showing a "Docker" service connected.

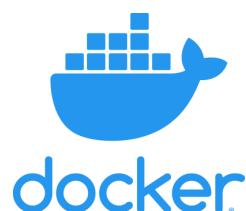

- In this file, you will define the steps required to build a **Docker image for MongoDB**. This Dockerfile specifies that you want to use the official **MongoDB image** as the base image, sets the working **directory to "/data"**, defines a mountable directory named **"./data/db"** (where the MongoDB data will be stored), exposes **port 27017**, and sets **"mongod"** as the command to run when the container launches.
- iv. Make sure to **save both of these Dockerfiles** in their respective directories.
  - v. Make sure to add "**Requirements.txt**" in the root folder as well. Specifying all the **packages and dependencies** on which our project works.

e. **Build the Docker images**:

- i. Open the terminal or **command prompt** in the root directory of your application.
- ii. Navigate and run the following **command to build the Docker image** for the application:
  - cd "**C:\Users\User\Desktop\Kaiburr-main\Kaibur-Tasks\Task 1**"
  - `docker build -t myapp .`
  - Note: **Make sure to include the period (.)** at the end of the command to specify the **current directory** as the build context.

```

C:\ Command Prompt

C:\Users\User\Desktop\Kaiburr-main\Kaibur_Tasks\Task_1\mongodb>

```

iv. Collection of all the “**images created**” can be viewed at ‘**Docker Hub**’:

The screenshot shows the Docker Desktop interface. On the left, there's a sidebar with icons for Containers, Images, Volumes, Dev Environments (BETA), Extensions, and a 'Add Extensions' button. The main area is titled 'Images' with a 'Local' tab selected (indicated by a blue underline) and a 'Hub' tab. A red arrow points from the text above to the 'Local' tab. Below it, a table lists six images with columns for Name, Tag, Status, Created, Size, and Actions. The images listed are: myappservice (ca49db2c7e18), myapp (f224c532e9e6), mongodb (e49f7f14cd2c), arpitsh/myapp (bada7c3586ed), and mydockerhubusername/myapp (with a red arrow pointing to it). The table shows 6 items. At the bottom, status information includes RAM 4.10 GB, CPU 0.05%, Connected to Hub, and version v4.17.1.

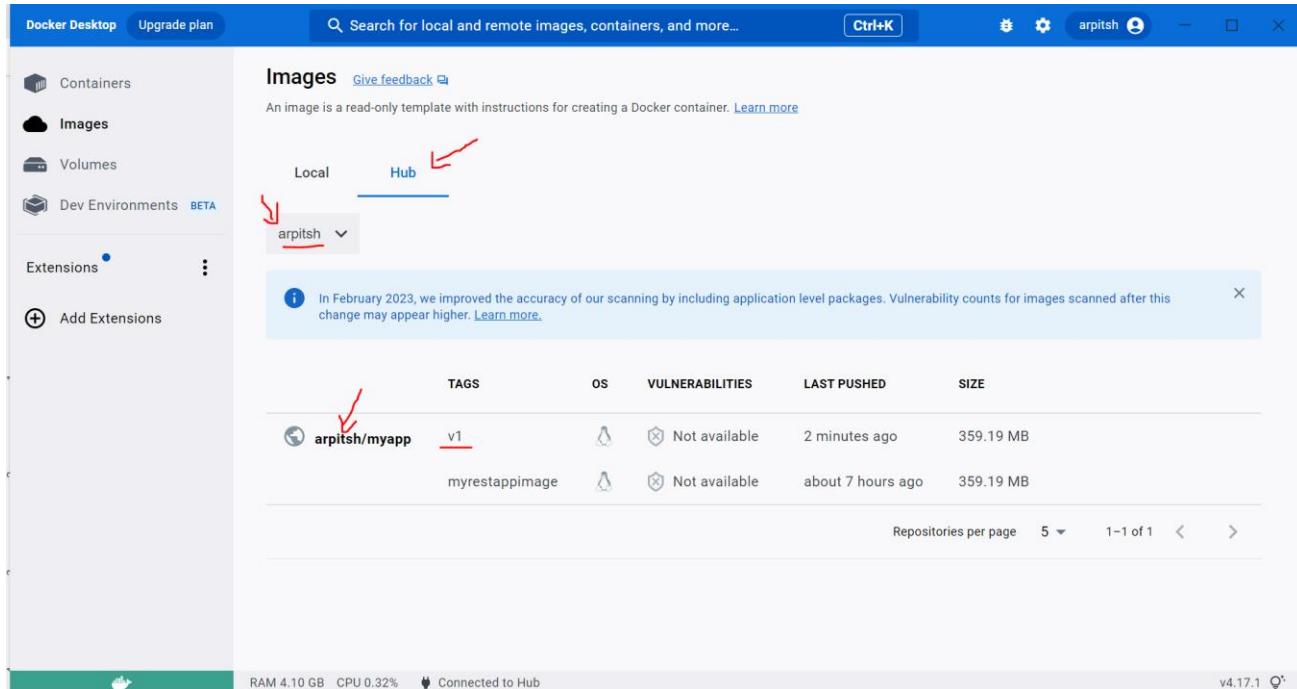

Name	Tag	Status	Created	Size	Actions
myappservice	latest	Unused	less than a minute ago	448.93 MB	...
myapp	latest	Unused	13 minutes ago	929.87 MB	...
mongodb	latest	Unused	about 7 hours ago	448.93 MB	...
arpitsh/myapp	myrestappimage	In use	about 8 hours ago	929.87 MB	...
mydockerhubusername/myapp					

f. “**Publishing Docker Images in Hub**”:

- Once you have a Docker Hub account, log in to Docker Hub using the ‘**docker login command**’ in your terminal. Enter your Docker Hub **username and password** when prompted.
- Next, **tag your local Docker image** with the name of your **Docker Hub repository** using the docker tag command. The format of the command is:
  - `docker tag <local-image-name> <dockerhub-username>/<image-name>:<image-tag>`
  - For example, if your Docker Hub username is **arpitsh**, your image name is **myapp**, and your tag is **latest** (default tag), the command would be: `docker tag myapp arpitsh/myapp:latest`
  - Finally, **push** your Docker image to Docker Hub using the docker push command: `docker push <dockerhub-username>/<image-name>:<image-tag>`
  - Using the same example as above, the command would be: `docker push arpitsh/myapp:latest`

## **Example:**

- ❖ My image name here is “**myapp**” and by default it has tag ‘**latest**’ and my username is “**arpitsh**” as registered with docker cloud, and I created a ‘**public repository named myapp**.’

Docker Desktop Upgrade plan

Search for local and remote images, containers, and more... Ctrl+K

Images Give feedback

An image is a read-only template with instructions for creating a Docker container. [Learn more](#)

Local Hub ↑

arpitsh ↓

In February 2023, we improved the accuracy of our scanning by including application level packages. Vulnerability counts for images scanned after this change may appear higher. [Learn more](#)

	TAGS	OS	VULNERABILITIES	LAST PUSHED	SIZE
	arpitsh/myapp v1		Not available	2 minutes ago	359.19 MB
	myrestappimage		Not available	about 7 hours ago	359.19 MB

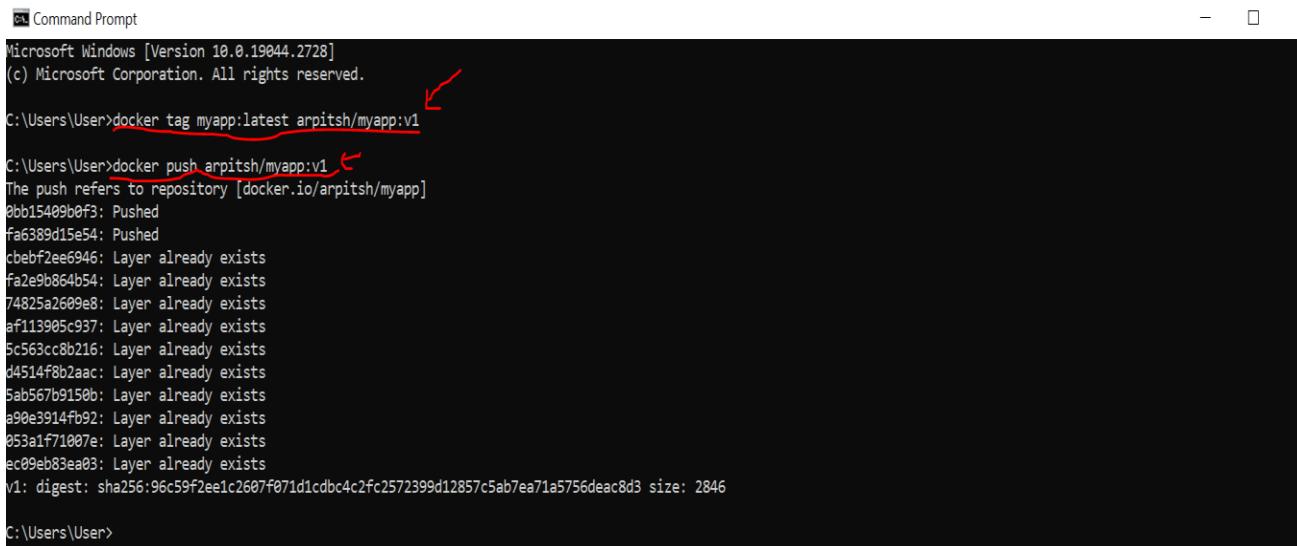

Repositories per page 5 1–1 of 1 < >

RAM 4.10 GB CPU 0.32% Connected to Hub v4.17.1

- ❖ So, my personal repository becomes now “**arpitsh/myapp**” and I want to push my image with tag “**v1**”.
- ❖ I “**tagged**” as below :  
➤ **docker tag myapp:latest arpitsh/myapp:v1**

- ❖ **Pushed the image** to my personal docker repository as below:

➤ **docker push arpitsh/myapp:v1**

```
Command Prompt
Microsoft Windows [Version 10.0.19044.2728]
(c) Microsoft Corporation. All rights reserved.

C:\Users\User>docker tag myapp:latest arpitsh/myapp:v1 ↑
C:\Users\User>docker push arpitsh/myapp:v1 ↑
The push refers to repository [docker.io/arpitsh/myapp]
0bb15409b0f3: Pushed

C:\Users\User>
```

iii. Similarly we **push the docker image “myappservice”** that represents the “**mongodb Dockerfile**”:

- Tag : **docker tag myappservice:latest  
arpitsh/myapp: mongo**
- Push : **docker push arpitsh/myapp: mongo**

The screenshot shows a Windows Command Prompt window titled "Command Prompt". The command entered is "C:\Users\User>docker tag myappservice:latest arpitsh/myapp: mongo". A red arrow points from the text "Tag : docker tag myappservice:latest arpitsh/myapp: mongo" in the previous slide to this command. Below it, another command "C:\Users\User>docker push arpitsh/myapp: mongo" is shown, with a red arrow pointing from the text "Push : docker push arpitsh/myapp: mongo" in the previous slide to this command. The output of the push command is displayed, showing a list of pushed images with their SHA-256 digests and sizes.

```
Microsoft Windows [Version 10.0.19044.2728]

C:\Users\User>
```

## 2. **Create Kubernetes manifests:**

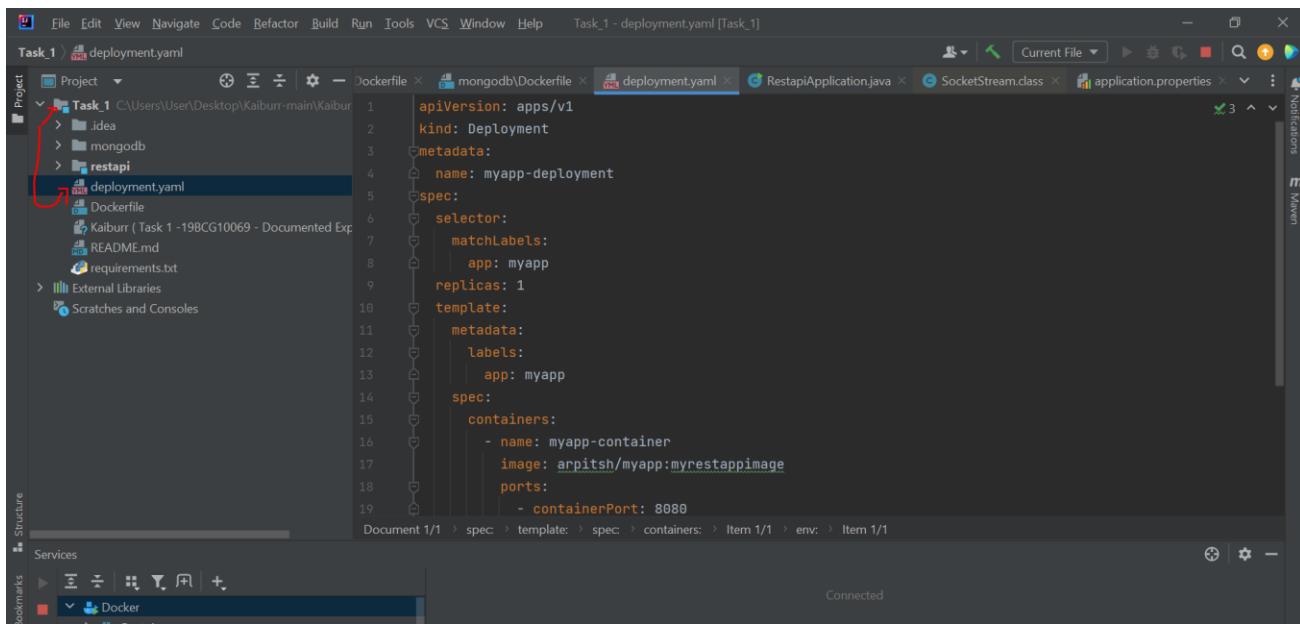

Next, you need to create “**Kubernetes manifests for your application**”. You need to create at least **a deployment and a service**. The deployment manifest specifies the **container image, the number of replicas, and any environment variables** that your application requires. The service manifest specifies how your application should be **exposed to the network**. You can use either a **LoadBalancer** (**I used this**) or NodePort service or an Ingress.

### a. **Creating ‘deployment.yaml’:**

- i. Create a **new file in the root directory** of your project called '**deployment.yaml**' and open it in a **text editor (like VsCode)**.  
**C:\Users\User\Desktop\Kaiburr-main\Kaibur\_Tasks\Task\_1**

- ii. Inside this "**Task1**" Create a "**deployment.yaml**" with the '**Following code**:

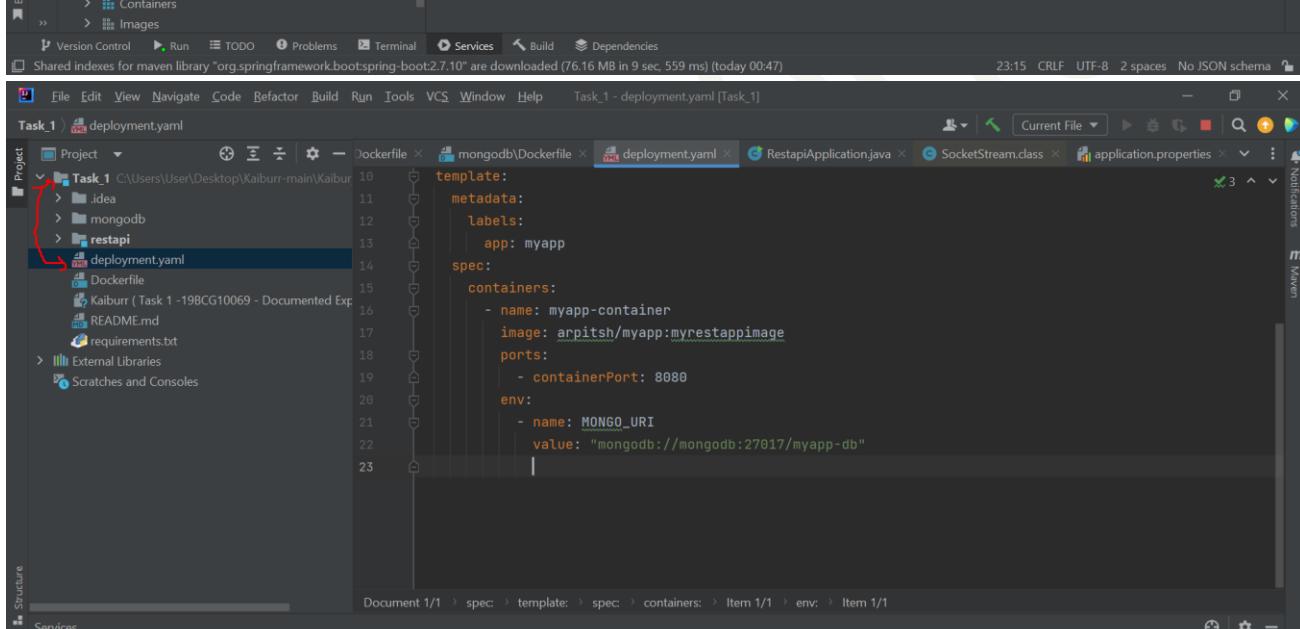

```

apiVersion: apps/v1
kind: Deployment
metadata:
  name: myapp-deployment
spec:
  selector:
    matchLabels:
      app: myapp
  replicas: 1
  template:
    metadata:
      labels:
        app: myapp
    spec:
      containers:
        - name: myapp-container
          image: arpitsh/myapp:myrestappimage
          ports:
            - containerPort: 8080

```

```

template:
  metadata:
    labels:
      app: myapp
  spec:
    containers:
      - name: myapp-container
        image: arpitsh/myapp:myrestappimage
        ports:
          - containerPort: 8080
    env:
      - name: MONGO_URI
        value: "mongodb://mongodb:27017/myapp-db"

```

### iii. “Save and close the deployment.yaml” file.

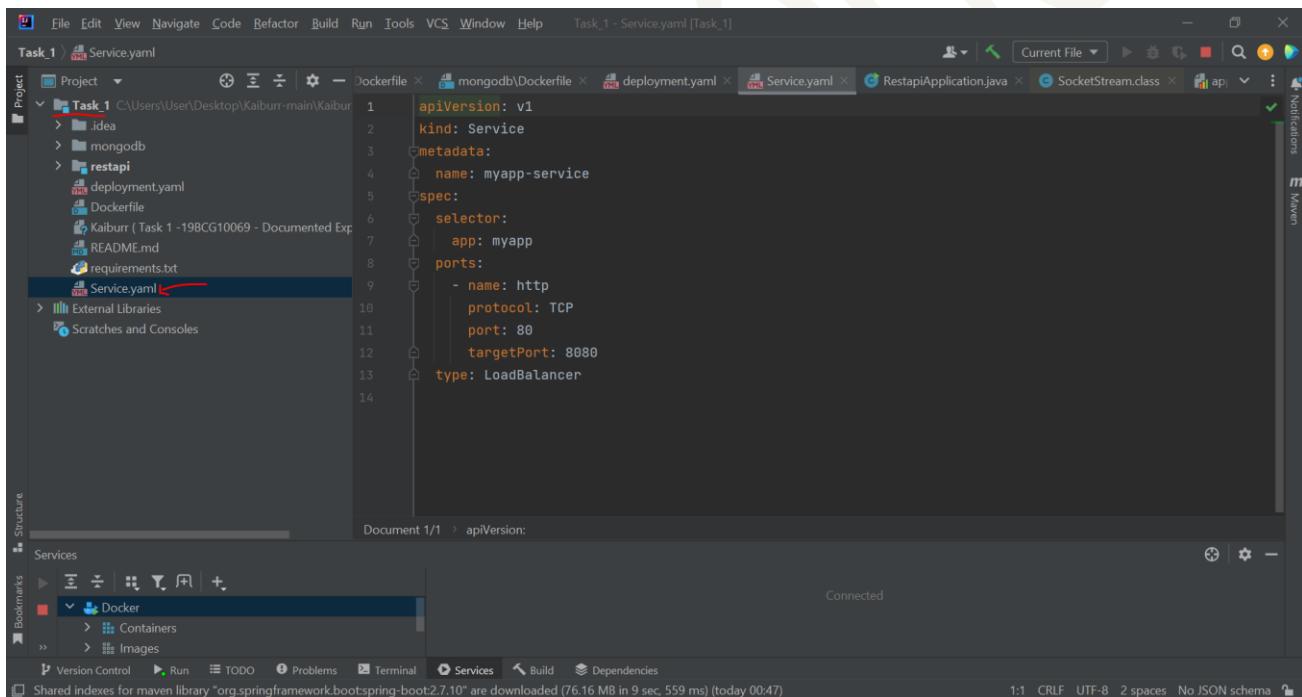

- In this deployment manifest, we have specified the ***name of the deployment, the number of replicas, and the container image*** to be used for the deployment. We have also specified the name of the ***MongoDB service*** that we will create in the next step.

- We have also defined an ***environment variable*** ***MONGO\_URI*** which contains the URL of the MongoDB database. Here, we have specified the name of the MongoDB service as `mongodb` and the name of the database as `myapp-db`.

b. ***Creating ‘Service.yaml’:***

- i. Create a ***new file in the root directory*** of your project called ‘`Service.yaml`’ and open it in a ***text editor (like VsCode)***.  
***“C:\Users\User\Desktop\Kaiburr-main\Kaibur\_Tasks\Task\_1”***
- ii. Inside this “***Task1***” Create a “***Service.yaml***” with the ‘***Following code***’:

```

apiVersion: v1
kind: Service
metadata:
  name: myapp-service
spec:
  selector:
    app: myapp
  ports:
    - name: http
      protocol: TCP
      port: 80
      targetPort: 8080
  type: LoadBalancer

```

iii. ***“Save and close the Service.yaml” file.***

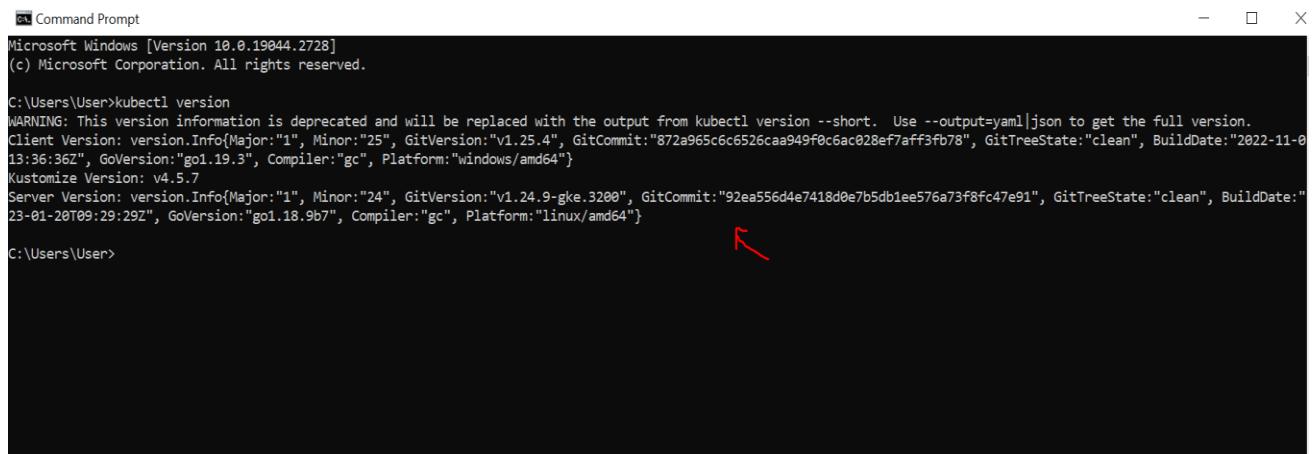

- This manifest ***creates a Kub"ernetes service*** that ***exposes your application on port “80”***, and forwards ***traffic to port 8080*** on the pods that match the “***app: myapp***” label selector (which should match the pods created by your ***deployment***).

### **3. Installing kubectl and Create Kubernetes cluster:**

- a. To “**install kubectl**”, you can follow the instructions provided by the Kubernetes documentation, which can be found here: <https://kubernetes.io/docs/tasks/tools/install-kubectl/>. The installation process depends on your operating system, so make sure to select the appropriate guide for your system.

❖ “**Successful Installation**” can be checked as follows(‘**kubectl –version**’):

```
C:\Users\User>kubectl version
WARNING: This version information is deprecated and will be replaced with the output from kubectl version --short. Use --output=yaml|json to get the full version.
Client Version: version.Info{Major:"1", Minor:"25", GitVersion:"v1.25.4", GitCommit:"872a965c6c6526caa949f0c6ac028ef7aff3fb78", GitTreeState:"clean", BuildDate:"2022-11-01T13:36:36Z", GoVersion:"go1.19.3", Compiler:"gc", Platform:"windows/amd64"}
Kustomize Version: v4.5.7
Server Version: version.Info{Major:"1", Minor:"24", GitVersion:"v1.24.9-gke.3200", GitCommit:"92ea556d4e7418d0e7b5db1ee576a73f8fc47e91", GitTreeState:"clean", BuildDate:"2023-01-20T09:29:29Z", GoVersion:"go1.18.9b7", Compiler:"gc", Platform:"linux/amd64"}
```

### **b. Creating “Kubernetes Cluster ” (kaiburcluster - V. IMP.):**

- i. To create a **Kubernetes cluster**, you have several options depending on your needs and resources. Here are a few options to consider:
  - **Create a cluster using a cloud provider:** Many cloud providers offer managed Kubernetes services, such as Amazon EKS, Google Kubernetes Engine, and Microsoft Azure Kubernetes Service. These services can help you quickly create and manage a Kubernetes cluster in the cloud.
  - **Create a cluster using Kubernetes distributions:** Kubernetes distributions, such as Rancher and OpenShift, provide preconfigured Kubernetes clusters that you can deploy on your own infrastructure.
  - **Create a cluster using Kubernetes installers:** Kubernetes installers, such as kubeadm and kops, allow you to create and configure a Kubernetes cluster on your own infrastructure. These tools require more setup and configuration compared to managed services.

configuration than cloud providers or Kubernetes distributions.

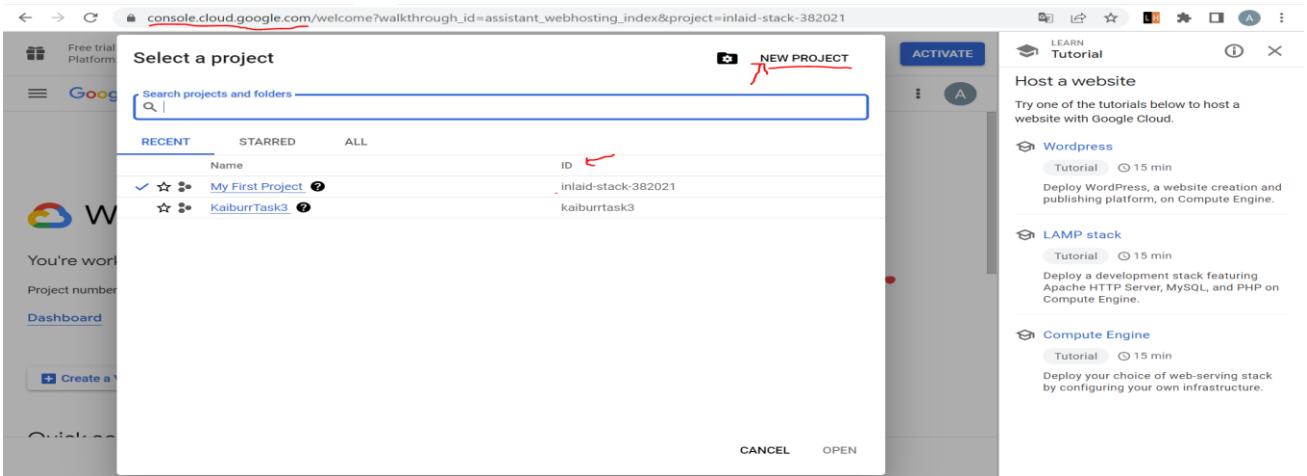

### **Google Kubernetes Engine (GKE):**

- One of the **easiest ways** to create a Kubernetes cluster is by using a managed Kubernetes service provided by a cloud provider. For the **purpose of this example**, I will show you how to create a **cluster using Google Kubernetes Engine** (GKE).
- Step 1: Create a Google Cloud Platform (**GCP account**) if you don't already have one. You can sign up for a free trial at <https://cloud.google.com/free>.

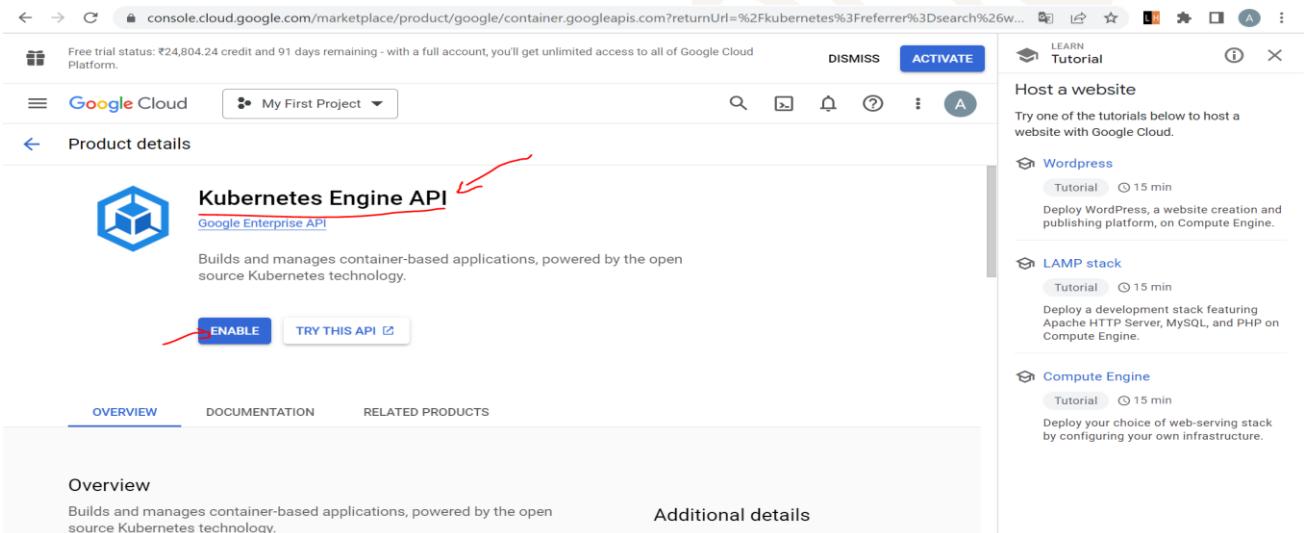

A screenshot of a web browser showing the Google Cloud homepage. The URL in the address bar is "cloud.google.com/free". The page features a large banner with the text "Solve real business challenges on Google Cloud" and two buttons: "Contact sales" and "Go to console". Below the banner, there are three sections: "Run workloads for free", "20+ free products for all customers", "\$300 in free credits for new customers", and "Additional free credits for businesses". A red arrow points from the text "Run workloads for free" towards the "Go to console" button.

- Step 2 : Once you have a GCP account, go to the '**GCP Console**' at <https://console.cloud.google.com/> and create a ***new project***.

→ Step 3 : Enable the **Kubernetes Engine API** by going to the **API Library** and searching for "**Kubernetes Engine API**". Then, click on "**Enable**".

→ Step 4 : Install the “**Google Cloud SDK**” on your local machine. You can download it from <https://cloud.google.com/sdk/docs/install>.

→ Step 5 : Once the SDK is installed, open a terminal and **authenticate with your GCP account** by running the command:

◆ `gcloud auth login`

Microsoft Windows [version 10.0.19044.2728]  
(c) Microsoft Corporation. All rights reserved.

```
C:\Users\user>gcloud auth login
Your browser has been opened to visit:

https://accounts.google.com/o/oauth2/auth?response_type=code&client_id=32555940559.apps.googleusercontent.com&redirect_uri=http%3A%2F%2Flocalhost%3A8085%2F&scope=openid+https%3A%2F%2Fwww.googleapis.com%2Fauth%2Fuserinfo.email+https%3A%2F%2Fwww.googleapis.com%2Fauth%2Fcloud-platform+https%3A%2F%2Fwww.googleapis.com%2Fauth%2Fappengine.admin+https%3A%2F%2Fwww.googleapis.com%2Fauth%2Fsqlservice.login+https%3A%2F%2Fwww.googleapis.com%2Fauth%2Fcompute+https%3A%2F%2Fwww.googleapis.com%2Fauth%2Faccounts.readOnly+e=3PO6G0i0ALD1bg1GPqHdVbJljo&access_type=offline&code_challenge=3TngLs1v7YjcsuJuPQnla0ZD2ls64-8OepmRtW&code_challenge_method=S256
```

You are now logged in as [arpit321@gmail.com].  
Your current project is [kaiburrtask3]. You can change this setting by running:  
\$ gcloud config set project PROJECT\_ID

Information about command-line tools and client libraries  
To learn more about Google Cloud CLI commands, see the [gcloud CLI guide](#).  
To learn more about the command-line tools for App Engine, Compute Engine, Cloud Storage, BigQuery, Cloud SQL, and Cloud DNS (which are all bundled with the gcloud CLI), see [Accessing services with the gcloud CLI](#).

→ Step 6 : ‘***Set the default project***’ for the SDK by running the command:

- ◆ `gcloud config set project <PROJECT_ID>`
- ◆ Replace ‘**<PROJECT\_ID>**’ with the ‘**ID**’ of the project you created in ‘**Step 2**’. Ex : “***gcloud config set project kaiburrtask3***”

```
C:\Users\User>gcloud config set project kaiburrtask3
Updated property [core/project].
C:\Users\User>
```

→ Step 7 : ***Create*** a “**Kubernetes cluster**” using the following command:

- ◆ `gcloud container clusters create <CLUSTER_NAME> --num-nodes=<NUM_NODES> --zone=<ZONE>`
- ◆ Replace **<CLUSTER\_NAME>** with the name you want to give your **cluster**, **<NUM\_NODES>** with the **number of nodes** you want to create, and **<ZONE>** with the **Google Cloud zone** where you want to create the cluster. Ex : “***gcloud container clusters create kaiburrtask3 --num-nodes=1 --zone=asia-south1-a***”
- ◆ This creates a cluster named kaiburrtask3 with 1 node and zone as asia-south1-a.

→ Step 8 : After a few minutes, your cluster should be ready. You can ***check the status*** of your cluster by running the **command**:

- ◆ `gcloud container clusters list`
- ◆ This will *display a list of all the clusters in your project*, along with their status.

```
C:\Users\User>gcloud container clusters list
NAME          LOCATION      MASTER_VERSION  MASTER_IP      MACHINE_TYPE   NODE_VERSION    NUM_NODES  STATUS
kaiburrcluster  asia-south1-a  1.24.9-gke.3200  35.200.198.145  e2-medium     1.24.9-gke.3200  1          RUNNING
C:\Users\User>
```

#### 4. Deploying our Application to ‘Pods’:

##### a. Retrieving Cluster Credentials:

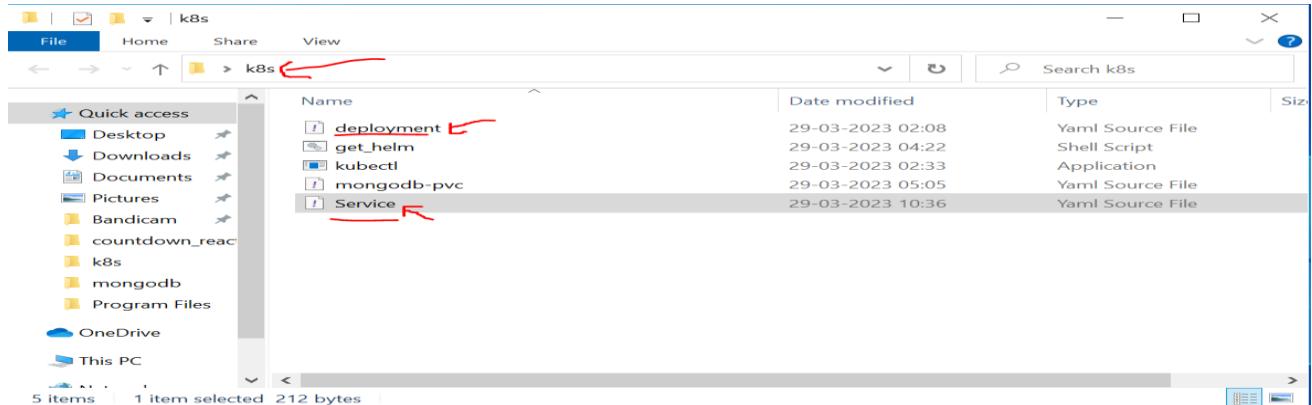

- Retrieve the cluster credentials: Depending on how you created your Kubernetes cluster, you may need to *retrieve the cluster credentials to authenticate with the cluster*. You can retrieve the credentials by using the *cloud provider's CLI tool* or by downloading the credentials file from the Kubernetes dashboard.
- “`gcloud container clusters get-credentials [CLUSTER_NAME] --zone [ZONE]`”**, replacing **[CLUSTER\_NAME]** with the name of your **GKE** cluster and **[ZONE]** with the zone where your cluster is **located**.
- `gcloud container clusters get-credentials kaiburrcluster --zone asia-south1-a`
- This command downloads the cluster credentials and *adds them to your local kubectl configuration file*, which enables you to *authenticate* with the cluster and execute Kubernetes commands

```
C:\Users\User>
C:\Users\User>gcloud container clusters get-credentials kaiburrcluster --zone asia-south1-a
Fetching cluster endpoint and auth data.
kubeconfig entry generated for kaiburrcluster.
C:\Users\User>
```

- ❖ Folder Creation (Optional - for Convenience) :

- I created a **Folder named “k8s”** having all the **yaml files** from which the **pods and deployment** had to be created. (**Service.yaml/deployment.yaml**)

- **get\_helm and mongodb-pvc discussed later.**

**b. Deploying the App (deployment.yaml):**

- Go to the “**k8s**” folder or wherever you have stored **“deployment.yaml”**.
  - cd “**C:\Users\User\Desktop\k8s**”
  - cd ‘**C:\Users\User\Desktop\Kaiburr-main\Kaibur\_Tasks\Task\_1**’
- Run the following command to **create the deployment**:
  - “**kubectl apply -f deployment.yaml**”

```
C:\Users\User\Desktop\k8s>kubectl apply -f deployment.yaml
deployment.apps/myapp-deployment unchanged
```

- Like this our **Application is deployed** on the remote cloud server.

**c. Deploying the Service (Service.yaml):**

- Go to the “**k8s**” folder or wherever you have stored **“Service.yaml”**.
  - cd “**C:\Users\User\Desktop\k8s**”
  - cd ‘**C:\Users\User\Desktop\Kaiburr-main\Kaibur\_Tasks\Task\_1**’
- Run the following command to **create the deployment**:
  - “**kubectl apply -f Service.yaml**”

```
C:\Users\User\Desktop\k8s>kubectl apply -f Service.yaml  
service/myapp-service configured
```

iii. Like this our **Service is deployed** on the remote cloud server.

- Verify that the deployment and service are created and running by running the following command:

- “**kubectl get all**”

```
C:\Users\User>kubectl get all  
NAME                                     READY   STATUS        RESTARTS   AGE  
pod/mongodb-849d55bbb6-nn4cm            1/1     Running      0          8h  
pod/myapp-deployment-7fcf74c859-29vzk  0/1     CrashLoopBackOff 120 (3m36s ago)  9h  
  
NAME           TYPE      CLUSTER-IP    EXTERNAL-IP  PORT(S)  AGE  
service/kubernetes  ClusterIP  10.20.0.1    <none>       443/TCP  10h  
service/mongodb  ClusterIP  10.20.2.21  <none>       27017/TCP 9h  
service/myapp-service  LoadBalancer  10.20.13.191  35.244.15.67  80:30370/TCP  9h  
  
NAME           READY   UP-TO-DATE  AVAILABLE  AGE  
deployment.apps/mongodb                   1/1     1          1          9h  
deployment.apps/myapp-deployment         0/1     1          0          9h  
  
NAME           DESIRED  CURRENT  READY   AGE  
replicaset.apps/mongodb-68b4fd77c6      0        0        0        9h  
replicaset.apps/mongodb-849d55bbb6      1        1        1        8h  
replicaset.apps/myapp-deployment-7fcf74c859  1        1        0        9h  
  
C:\Users\User>
```

- This command will show you a **list of all the resources** in your Kubernetes cluster. You should see **your deployment and service listed**.

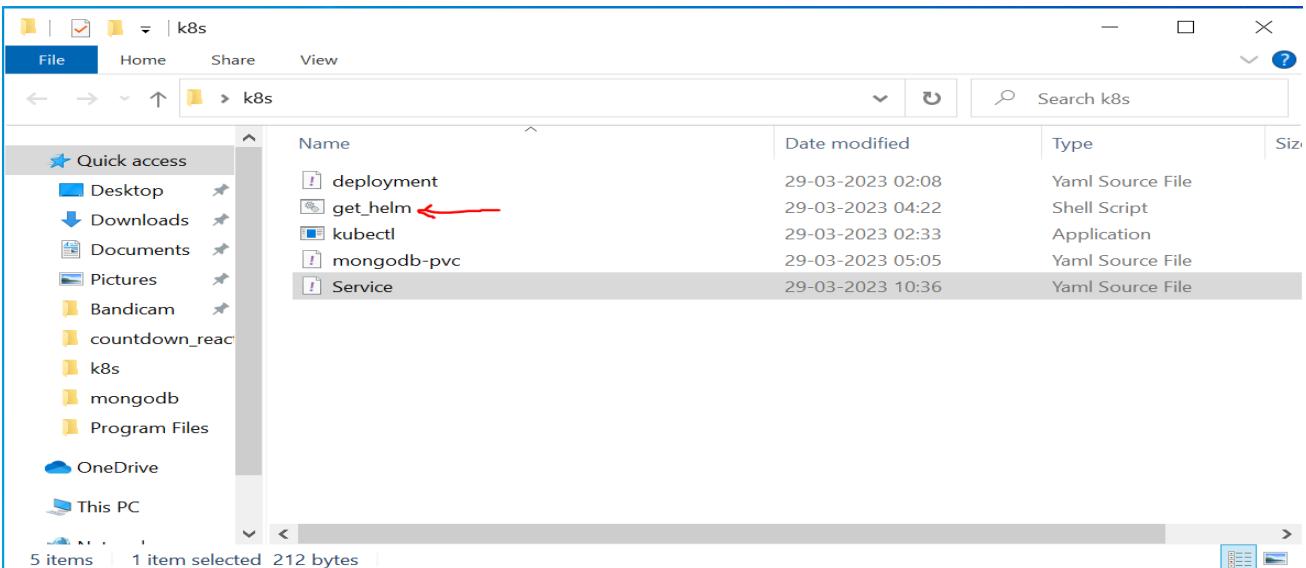

## 5. Deploy MongoDB to the cluster:

To deploy **MongoDB to the cluster**, you can use a community **Helm chart**. Helm is a package manager for Kubernetes that allows you to **easily install and manage applications**. You can install Helm by following the instructions on the Helm website.

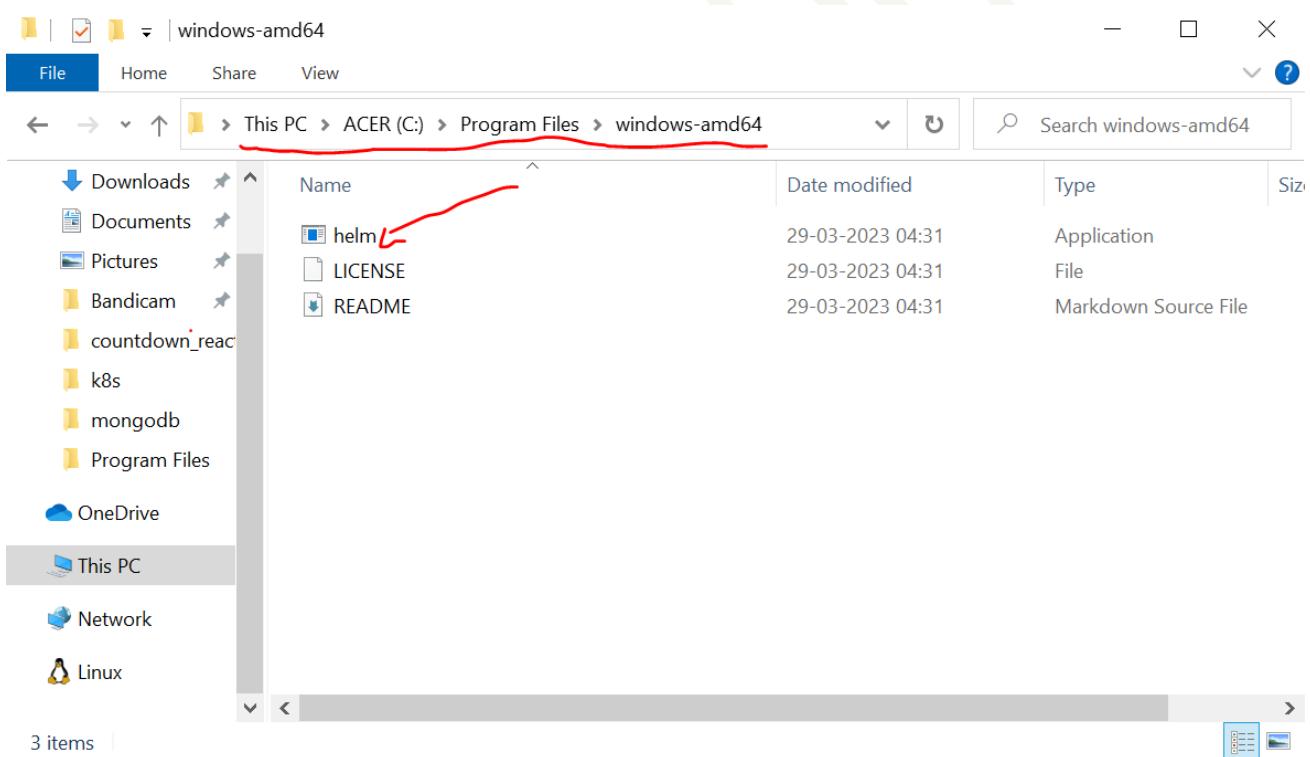

- a. **Installing Helm & Adding MongoDB:**

- i. ‘**Install Helm**’ by following the instructions on the Helm website: <https://helm.sh/docs/intro/install/>. I downloaded the **package and unzipped it in the “k8s”** folder that we created earlier. I did so that all these files can be put together for convenience.

ii. Go to the Directory where '**helm.exe**' is installed: (**C:\Program Files\windows-amd64**)

iii. Once Helm is installed, add the '**Bitnami repository**' by running the following command:

- '**helm repo add bitnami https://charts.bitnami.com/bitnami**'

```
C:\Program Files\windows-amd64>helm repo add bitnami https://charts.bitnami.com/bitnami  
"bitnami" has been added to your repositories
```

- iv. **Update the Helm** repository by running the following command:
- ‘**helm repo update**’

```
C:\Program Files\windows-amd64>helm repo update  
Hang tight while we grab the latest from your chart repositories...  
...Successfully got an update from the "bitnami" chart repository  
Update Complete. Happy Helming!
```

- v. **Update the Helm** repository by running the following command:
- ‘**helm repo update**’

```
C:\Program Files\windows-amd64>helm install mongodb bitnami/mongodb  
NAME: mongodb  
LAST DEPLOYED: Wed Mar 29 04:41:32 2023  
NAMESPACE: default  
STATUS: deployed  
REVISION: 1  
TEST SUITE: None  
NOTES:  
CHART NAME: mongodb  
CHART VERSION: 13.9.3  
APP VERSION: 6.0.5  
** Please be patient while the chart is being deployed **  
MongoDB&reg; can be accessed on the following DNS name(s) and ports from within your cluster:  
mongodb.default.svc.cluster.local  
To get the root password run:  
export MONGODB_ROOT_PASSWORD=$(kubectl get secret --namespace default mongodb -o jsonpath=".data.mongodb-root-password" | base64 -d)  
To connect to your database, create a MongoDB&reg; client container:  
kubectl run --namespace default mongodb-client --rm --tty -i --restart='Never' --env="MONGODB_ROOT_PASSWORD=$MONGODB_ROOT_PASSWORD" --image docker.io/bitnami/mongodb:6.0.5-debian-11-r1 --command -- bash  
Then, run the following command:  
mongosh admin --host "mongodb" --authenticationDatabase admin -u root -p $MONGODB_ROOT_PASSWORD  
To connect to your database from outside the cluster execute the following commands:  
kubectl port-forward --namespace default svc/mongodb 27017:27017 &  
mongosh --host 127.0.0.1 --authenticationDatabase admin -p $MONGODB_ROOT_PASSWORD
```

- *This command installs the latest version of the MongoDB chart from the Bitnami repository.*

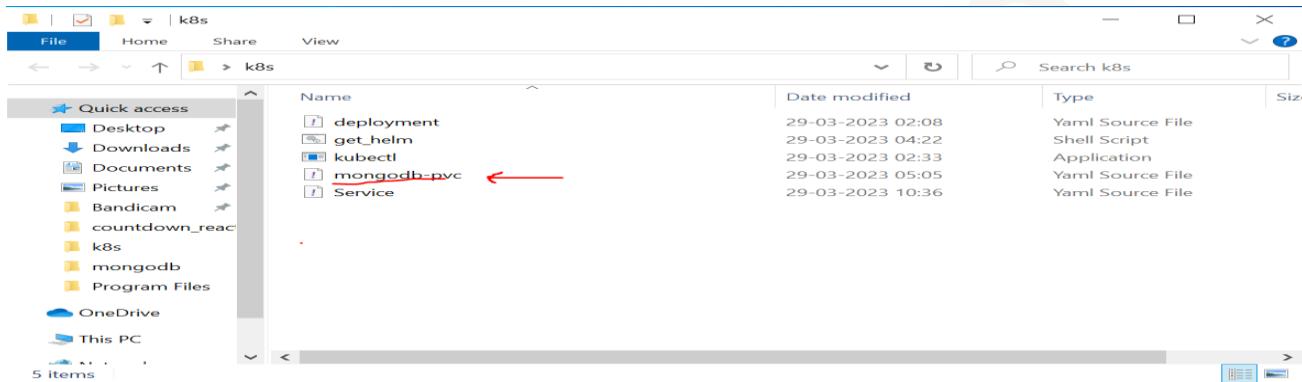

b. **Configure persistent storage:**

- Finally, you need to **configure persistent storage for MongoDB**. This ensures that the **data stored in the database is not lost** when the pod is deleted. To configure persistent storage, you can create a

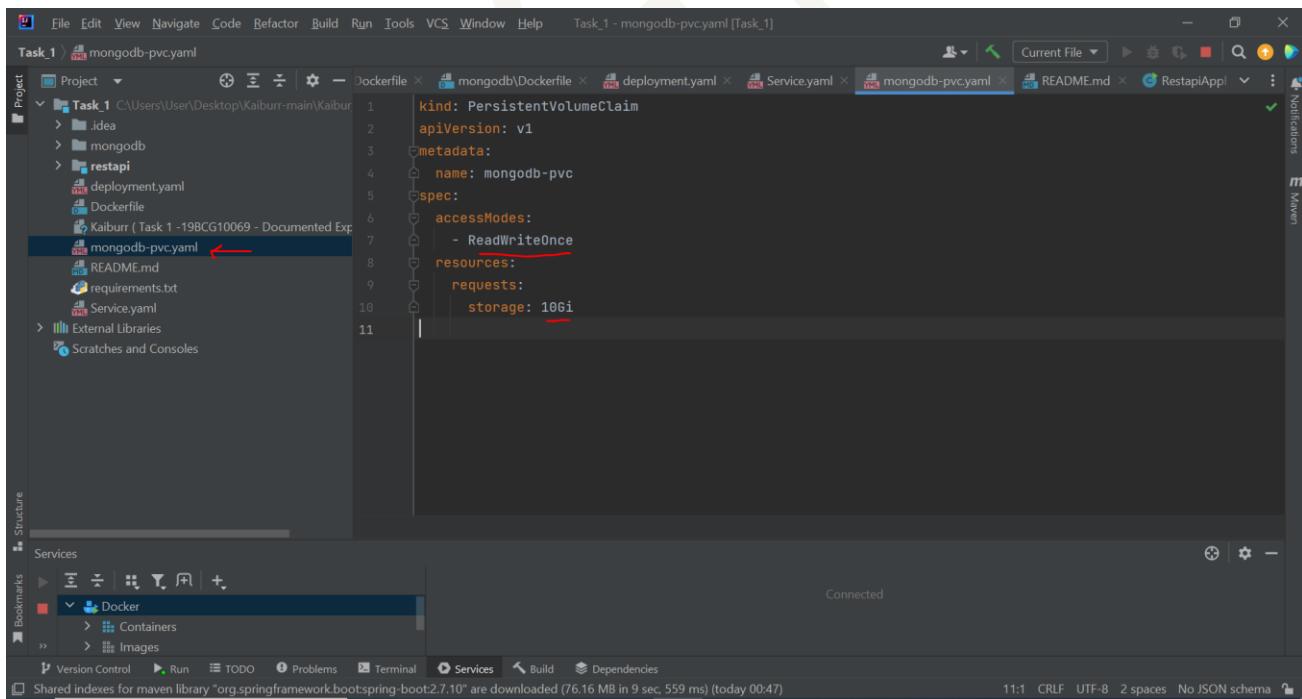

**PersistentVolumeClaim and attach it to the MongoDB pod.** The PersistentVolumeClaim **specifies the storage requirements**, and the PersistentVolume provides the actual storage.

ii. **Create** a PersistentVolumeClaim (**PVC**) **YAML file**:

- **Navigate to “k8s” Folder** or wherever all the **YAML files** are stored.

- Create a file named “**mongodb-pvc.yaml**” and add the **following YAML code** to it:

- This **YAML code creates a PersistentVolumeClaim named ‘mongodb-pvc’ with ReadWriteOnce access mode and requests 10Gi of storage.**

### iii. Apply PersistentVolumeClaim (PVC) - mongodb-pvc.yaml:

- If you used **Helm to deploy MongoDB**, you can modify the deployment using the **following command**:
- “**helm upgrade --install mongodb bitnami/mongodb --set persistence.existingClaim=mongodb-pvc**”

```
C:\Program Files\windows-amd64>helm upgrade --install mongodb bitnami/mongodb --set persistence.existingClaim=mongodb-pvc
Release "mongodb" has been upgraded. Happy Helm-ing!
NAME: mongodb
LAST DEPLOYED: Wed Mar 29 05:17:38 2023
NAMESPACE: default
STATUS: deployed
REVISION: 2
TEST SUITE: None
NOTES:
CHART NAME: mongodb
CHART VERSION: 13.9.3
APP VERSION: 6.0.5

** Please be patient while the chart is being deployed **

MongoDB&reg; can be accessed on the following DNS name(s) and ports from within your cluster:
  mongodb.default.svc.cluster.local

To get the root password run:
  export MONGODB_ROOT_PASSWORD=$(kubectl get secret --namespace default mongodb -o jsonpath=".data.mongodb-root-password" | base64 -d)

To connect to your database, create a MongoDB&reg; client container:
  kubectl run --namespace default mongodb-client --rm --tty -i --restart='Never' --env="MONGODB_ROOT_PASSWORD=$MONGODB_ROOT_PASSWORD" --image docker.io/bitnami/mongodb:6.0.5-debian-11-r1 --command -- bash

Then, run the following command:
  mongosh admin --host "mongodb" --authenticationDatabase admin -u root -p $MONGODB_ROOT_PASSWORD

To connect to your database from outside the cluster execute the following commands:
  kubectl port-forward --namespace default svc/mongodb 27017:27017 &
  mongosh --host 127.0.0.1 --authenticationDatabase admin -p $MONGODB_ROOT_PASSWORD
```

- This command **upgrades the existing MongoDB deployment with the bitnami/mongodb chart and sets the persistence.existingClaim value to mongodb-pvc**, which tells Kubernetes to use the mongodb-pvc PersistentVolumeClaim for MongoDB's persistent storage.

**That's it!** With these steps, you have configured **persistent storage for MongoDB** on the cluster.

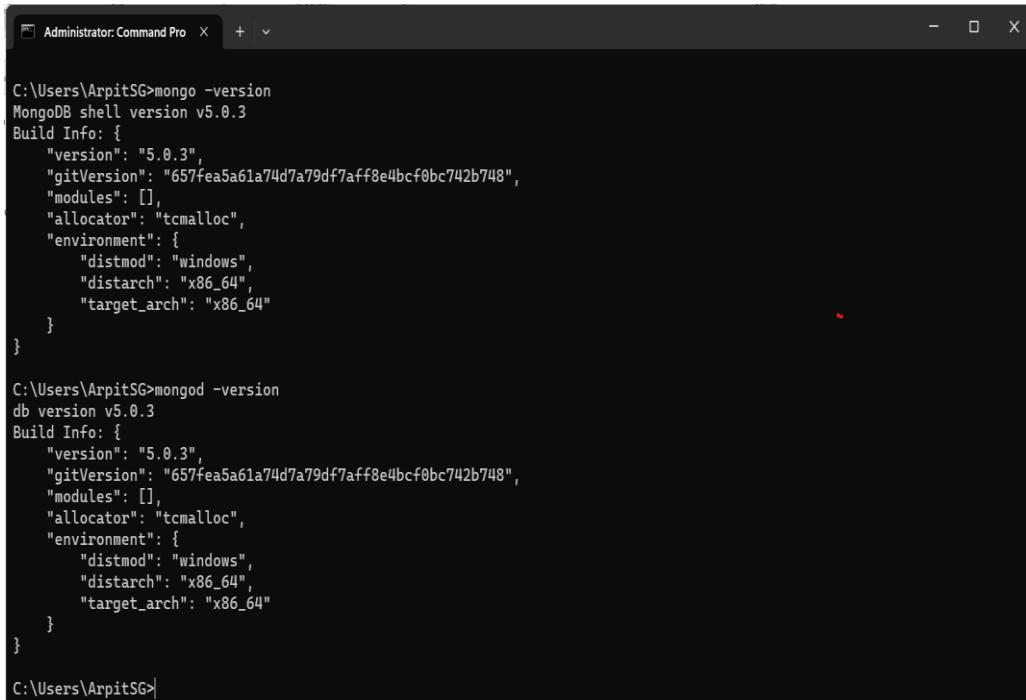

## 6. Verification of cluster:

- a. Run this command : `kubectl get services`

```
C:\Users\User>kubectl get service
NAME         TYPE      CLUSTER-IP   EXTERNAL-IP   PORT(S)   AGE
kubernetes   ClusterIP  10.20.0.1    <none>        443/TCP   11h
mongodb       ClusterIP  10.20.2.21   <none>        27017/TCP  10h
myapp-service LoadBalancer 10.20.13.191  35.244.15.67  80:30370/TCP  11h

C:\Users\User>
```

*That's it! You have now created Kubernetes manifests for your application and deployed them to your Kubernetes cluster.*

```
C:\Users\ArpitSG>mongo -version
MongoDB shell version v5.0.3
Build Info: {
    "version": "5.0.3",
    "gitVersion": "657fea5a61a74d7a79df7aff8e4bcf0bc742b748",
    "modules": [],
    "allocator": "tcmalloc",
    "environment": {
        "distmod": "windows",
        "distarch": "x86_64",
        "target_arch": "x86_64"
    }
}

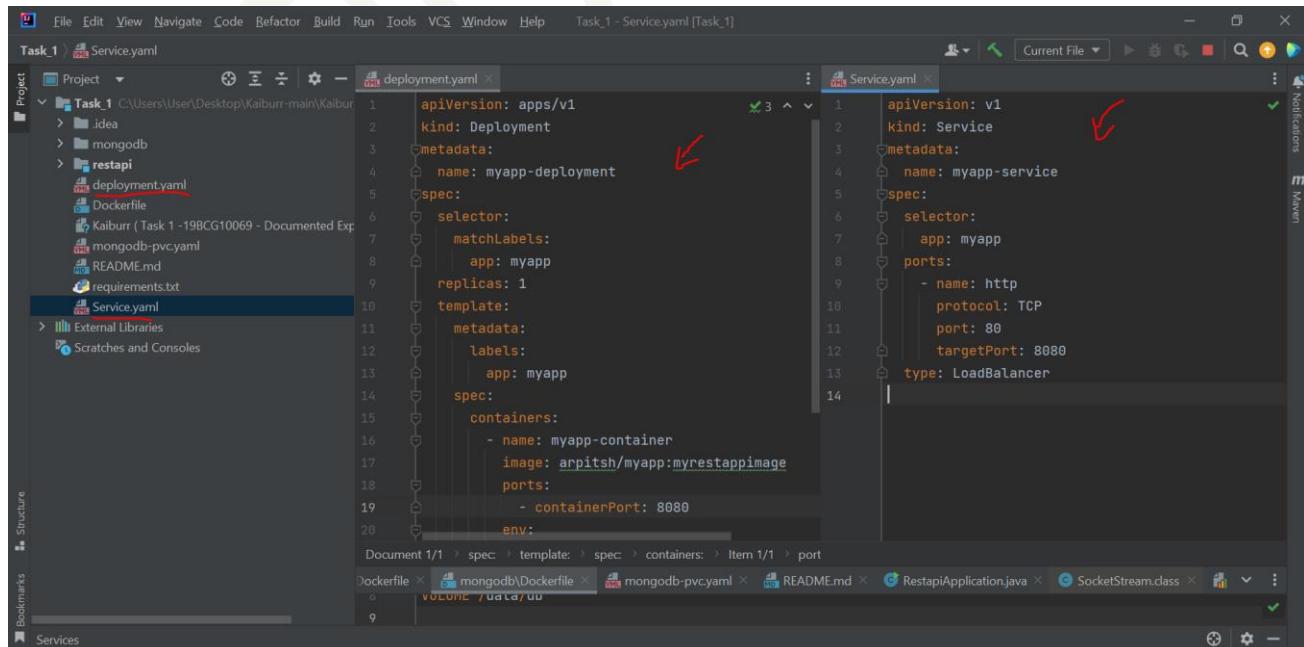

C:\Users\ArpitSG>mongod --version
db version v5.0.3
Build Info: {
    "version": "5.0.3",
    "gitVersion": "657fea5a61a74d7a79df7aff8e4bcf0bc742b748",
    "modules": [],
    "allocator": "tcmalloc",
    "environment": {
        "distmod": "windows",
        "distarch": "x86_64",
        "target_arch": "x86_64"
    }
}

C:\Users\ArpitSG>
```

## 7. API Testing/Output:

- you can bring your application up by applying your yaml manifests:

→ Yes.

```
deployment.yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: myapp-deployment
spec:
  selector:
    matchLabels:
      app: myapp
  replicas: 1
  template:
    metadata:
      labels:
        app: myapp
    spec:
      containers:
        - name: myapp-container
          image: arpitsh/myapp:myrestappimage
          ports:
            - containerPort: 8080
          env:
```

```
Service.yaml
apiVersion: v1
kind: Service
metadata:
  name: myapp-service
spec:
  selector:
    app: myapp
  ports:
    - name: http
      protocol: TCP
      port: 80
      targetPort: 8080
      type: LoadBalancer
```

- mongodb is running in a separate pod

→ Yes.

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)	AGE
kubernetes	ClusterIP	10.20.0.1	<none>	443/TCP	11h
<u>mongodb</u>	ClusterIP	10.20.2.21	<none>	27017/TCP	10h ↙
myapp-service	LoadBalancer	10.20.13.191	35.244.15.67	80:30370/TCP	11h

- the application should take mongo connection details from the environment variables

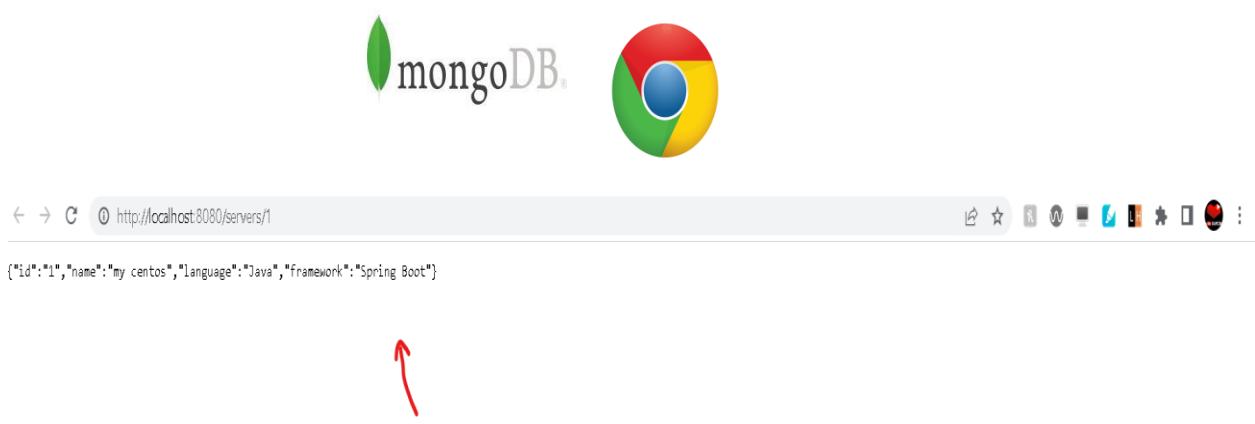

→ Yes.

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: myapp-deployment
spec:
  selector:
    matchLabels:
      app: myapp
  replicas: 1
  template:
    metadata:
      labels:
        app: myapp
    spec:
      containers:
        - name: myapp-container
          image: arpitsh/myapp:myrestappimage
          ports:
            - containerPort: 8080
          env: ↙
            - name: MONGO_URI
              value: "mongodb://mongodb:27017/myapp-db"
```

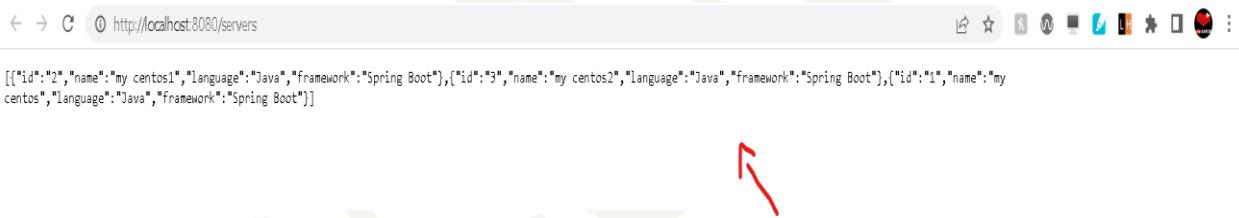

- the app endpoints should be available from your host machine

→ Yes.

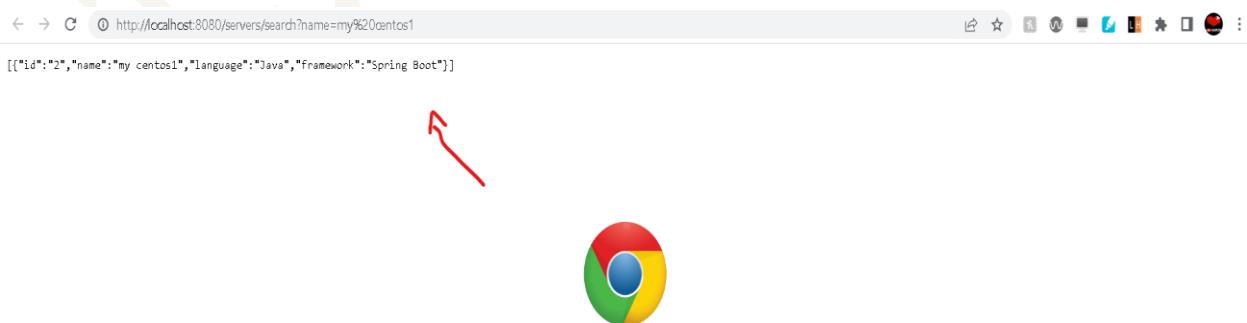

- a. To get a **single server by ID**, you can send a **GET** request to **<http://localhost:8080/servers/{id}>**, where {id} is the ID of the server you want to retrieve. Ex: **<http://localhost:8080/servers/1>**.

- b. To **get all servers**, you can send a **GET** request to  
**<http://localhost:8080/servers>.**

- c. To **search servers by name**, you can send a **GET** request to  
**<http://localhost:8080/servers/search?name={name}>**, where {name} is the name of the server you want to search for. Ex:  
**<http://localhost:8080/servers/search?name=my centos1>**.

- **a persistent volume should be used to store the MongoDB data**

→ Yes.

```

apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mongodb-pvc
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 10Gi

```

## Summary of the steps to create a Deploy your Application using kubernetes (Task 3):

1. Create Dockerfiles for your application and MongoDB instance.
2. Build Docker images using the command "docker build -t <image-name>:<version> <path-to-dockerfile>".
3. Create Kubernetes manifests, including at least a deployment and a service.
4. Install Helm and deploy MongoDB to the cluster using the command "helm install mongodb bitnami/mongodb".
5. Deploy your application to the cluster using the command "kubectl apply -f <path-to-manifests>".
6. Verify the deployment by accessing the endpoints from your host machine using the command "kubectl get services".
7. Configure persistent storage for MongoDB by creating a PersistentVolumeClaim and attaching it to the MongoDB pod.

## Explanation on Tools/Technology(s) Used:

❖ **Docker:**

- a. The purpose of using Docker in ***this project*** is to containerize the application and MongoDB instance. Docker allows developers to create lightweight, portable containers that include all the necessary dependencies and configuration to run an application. This makes it easy to deploy the application to different environments, such as a local development environment or a production server, without worrying about the differences in operating systems or system configurations. Additionally, Docker provides isolation between the application and the host system, which increases security and stability.

❖ **Kubernetes:**

- a. The purpose of using Kubernetes in ***this project*** is to orchestrate and manage the deployment, scaling, and management of containerized applications. Kubernetes provides a platform for automating the deployment, scaling, and management of containerized applications, including features such as self-healing, auto-scaling, and rolling updates.
- b. ***In this project***, Kubernetes is used to deploy and manage the Docker containers for the application and MongoDB instance, including scaling the number of replicas based on demand and managing the application's network connectivity and storage. Kubernetes also provides the ability to roll out updates to the application without downtime and roll back to previous versions if necessary, making it a powerful tool for managing and maintaining containerized applications in production.

❖ **Helm:**

- a. ***In this project***, Helm is used as a package manager for Kubernetes. Helm allows you to easily install, manage, and upgrade applications in your Kubernetes cluster. Instead of manually configuring all the components

required for the application, you can use a pre-configured chart that defines the application's deployment, service, and other necessary Kubernetes resources. The chart also allows you to customize the application configuration, such as specifying environment variables, resource limits, and storage requirements, which simplifies the process of deploying and managing the application in a Kubernetes cluster.

❖ **Google Cloud Provider:**

- a. The purpose of using ***Google Cloud provider in this project*** is to host and manage the Kubernetes cluster on the Google Cloud Platform. Google Cloud provides a managed Kubernetes service called Google Kubernetes Engine (GKE) that allows developers to deploy and manage containerized applications on Google Cloud. By using GKE, developers can easily create and manage a Kubernetes cluster without having to worry about the underlying infrastructure. GKE also provides features such as automatic scaling, load balancing, and monitoring, which make it easier to manage and scale the applications running on the cluster. Additionally, GKE integrates with other Google Cloud services such as Cloud Storage, BigQuery, and Pub/Sub, which can be used to build more complex and scalable applications.

**Thank You!**

---
